

# BEDROCK GEOLOGIC MAP OF DES MOINES COUNTY, IOWA

Ryan Clark, Stephanie Tassier-Surine, Phil Kerr, and Alyssa Bancroft  
Iowa Geological Survey, IIHR-Hydroscience & Engineering, University of Iowa, Iowa City, Iowa

Open File Map: OFM-23-1  
Keith Schilling, State Geologist  
Published June, 2023

**LEGEND**

**MAP SYMBOLS**

- bedrock outcrop
- GeoSam point
- new drill core
- geophysics point
- quarry
- unit contact - concealed
- cross-section
- town boundary
- hillshade

**STRUCTURE SYMBOLS**

- syncline moderate confidence, location concealed
- anticline moderate confidence, location concealed
- syncline low confidence, location concealed
- plunge direction

**ROAD CLASSIFICATION**

- U.S. Route
- State Route

**LITHOLOGIES**

- coal
- dolomite
- dolomitic shale
- fossiliferous limestone
- limestone
- lithographic limestone
- sandy limestone
- shale
- siltstone
- unlithified sediments

**LITHOLOGY SYMBOLS**

- geodes
- chert
- oolitic
- argillaceous zone
- breccia
- unconformity

## INTRODUCTION

Des Moines County is located on the Southern Iowa Drift Plain landform region, which is dominated by loess-mantled till plains in the uplands and fine- to coarse-grained alluvial deposits in stream valleys. The thickness of Quaternary materials overlying the bedrock surface varies widely across the county ranging from 0 to 23 m (0 - 75 ft), but can be up to 114 m (375 ft) thick in the eastern part of the mapping area. An accompanying map of the surficial geology of Des Moines County has been published concurrently with this map (Open File Map OFM-23-2; Tassier-Surine et al., 2023).

The bedrock surface of Des Moines County is dominated by strata of the Mississippian Subsystem that is riddled with deeply incised erosional channels, exposing shales of the Devonian System. Pennsylvanian units occur as minor erosional outliers in the southwestern part of the county. All data from previous STATEMAP quadrangle bedrock geologic maps in Des Moines County (Lowell, Danville, Sperry, and West Burlington) were incorporated into the Bedrock Geologic Map of Des Moines County.

The majority of the bedrock exposures in Des Moines County were found along the bluffs of the Skunk and Mississippi rivers that border the county, as well as along Flint Creek near the middle of the map area. Des Moines County hosts more than 20 aggregate rock quarries, most of which are abandoned. Geologic reconnaissance of 64 bedrock outcrops, three active quarries, and five abandoned quarries within the mapping area was conducted during field activities. Sixteen abandoned quarries were identified from historical aerial photography, LIDAR, and previously published reports. Additional subsurface information was derived from the analysis of more than 1,100 water well and borehole records, over 100 of which have cutting samples that were described as part of this mapping project, 32 passive seismic data points, and 33 well records in Illinois. For a more detailed account of data resources, mapping methods, and stratigraphy, please refer to the Summary Map Report of Des Moines County, Iowa.

## STRATIGRAPHIC COLUMN AND LEGEND

System	Subsystem	Series	Stage	Regional Series	Map Units (Map Symbols)	Lithology	Thickness (feet)	Lithostratigraphic Unit Description						
Carboniferous	Mississippian	Quaternary	Quaternary	Quaternary	Quaternary undifferentiated (Qu)	[Symbol]	0 to 75	<b>Qu - Undifferentiated Unconsolidated Sediments</b> - Consists of loamy soils developed in loess, glacial till, and colluvium of variable thickness, and alluvial clay, silt, sand, and gravel. The total thickness of Quaternary deposits typically varies between 0 and 23 m (0 - 75 ft) but can be up to 114 m (375 ft) thick in the eastern part of the mapping area. This unit is shown only on the cross-section, not on the map.						
							Pennsylvanian	Middle-Lower	Moscowian-Baskinian	Desmoinesian-Atkani-Moravian	Lower Cherokee Group (Pcl)	[Symbol]	0 to 45	<b>Pcl - Shale and Sandstone</b> - Pennsylvanian units occur as relatively thin erosional outliers reaching a maximum thickness of 14 m (45 ft) in the southwestern part of the mapping area. This unit consists of light to medium gray shale/mudstone that is partly silty to sandy, fine to medium quartz sandstone that is rarely conglomeratic, and coal. Some black shales are carbonaceous to phosphatic. Only one outcrop of this unit was identified in the mapping area.
													Middle	Viscum
		Lower	Tournaesian	Warsaw Formation (Mws)	[Symbol]	< 75	<b>Mws - Shale, Dolomite, and Limestone</b> - The Warsaw Formation varies in thickness due to erosional discontinuities at both the upper and lower contacts, reaching a maximum thickness of approximately 17 m (55 ft) within the mapping area. This unit can generally be divided into two major lithologic groupings, a lower argillaceous dolomite sequence and an upper shale-dominated sequence, however preservation is variable as either or both facies may exist in places. The upper shale is typically light to medium gray, silty, and variably dolomitic with minor chert, sand, and sparse quartz goodes. The lower dolomite, sometimes referred to as the "greed beds", is argillaceous to shaly, with scattered abundant quartz goodes. Minor limestone units occur locally as thin, irregular beds with crinoidal packstone-granulite fabrics. Brachiopods, echinoderms, bryozoans, solitary corals, and fish bones and teeth occur throughout this unit as both abundant debris and partially articulated specimens. Molds of sponge spicules can occur in the dolomite facies. Minor glauconite and locally abundant goodes are also associated with this unit. Calcite vug fills and rare sphaerulite are noteworthy. A total of 10 exposures (three quarries and 13 outcrops) of this unit were observed in the mapping area.							
						Lower	Tournaesian	Keokuk Formation (Mkeo)	[Symbol]	< 85	<b>Mkeo - Limestone, Dolomite, Chert, and Shale</b> - The Keokuk Formation averages about 19 m (65 ft) in thickness but can be up to 26 m (85 ft) thick in the mapping area. This unit is dominated by tan to gray interbedded skeletal limestones displaying packstone-granulite facies. Nodular to bedded chert, in part fossiliferous, is common in the lower half of the sequence. Variably argillaceous dolomite and thin shales also occur throughout the unit. The unit displays multiple background surfaces and bone beds with scattered abundant fish debris, the most prominent of these surfaces is a marker bed at the base of the formation (sometimes referred to as the Burlington-Keokuk or B-K bone bed). Brachiopods, crinoids, bryozoans, solitary corals, and fish bones and teeth occur throughout this unit as both abundant debris and partially articulated specimens. Molds of sponge spicules can occur in the dolomite facies. Minor glauconite and locally abundant goodes are also associated with this unit. Calcite vug fills and rare sphaerulite are noteworthy. A total of 16 exposures (three quarries and 13 outcrops) of this unit were observed in the mapping area.			
		Lower	Tournaesian	Burlington Formation (Mb)	[Symbol]					< 95	<b>Mb - Limestone, Dolomite, and Chert</b> - The Burlington Formation averages about 19 m (65 ft) in thickness but can be up to 29 m (95 ft) thick in the mapping area. This unit is subdivided into three members (in ascending order) the Dolbeek Creek, Haight Creek, and Burlington. The Dolbeek Creek Member is characterized by limestone and dark brown, unfossiliferous dolomite, nodular to bedded chert, occasional fish debris, and traces of glauconite. Its light color helps differentiate this unit from the dominantly gray packstones of the overlying Keokuk Formation. This unit dominates the bedrock surface in the mapping area with 47 exposures (16 quarry and 31 outcrops). The Warsaw, Keokuk, and Burlington formations are difficult to differentiate in the northern part of Des Moines County. They tend to thin towards the north-southwest, losing much of the fossiliferous limestone facies and becoming more dolomite-dominated.			
						Lower	Tournaesian	Kinderhookian formations (Mk)	[Symbol]	< 75	<b>Mk - Dolomite, Limestone, and Siltstone</b> - The Kinderhookian sequence reaches a maximum thickness of 23 m (75 ft) in the mapping area, generally thinning towards the north. This unit comprises three formations, in ascending order the Louisiana (formerly "McRaney"), Prospect Hill, and Wasserville, characterized by distinct lithologic groupings. The Louisiana Formation is composed of alternating beds of primarily fossiliferous, silt-lithographic limestone and dark brown, unfossiliferous dolomite, generating a unique "zebra-striped" appearance in outcrop. Calcite vug fills are common and a basal oolite is locally present. The Prospect Hill Formation is a light to medium gray, dolomitic siltstone that grades to shale in some locations. This unit is often laminated with vertical and horizontal burrow fabrics and faint cross-stratified bedforms. Fossils are rare to absent although fossil molds are locally abundant. The Wasserville Formation, which now includes the former Starr's Cave Member at the basal member, consists of massive dolomite with variable chert that grades into dolomitic limestone lower in the section. The basal Starr's Cave Member is a fossiliferous limestone with packstone-granulite facies and is commonly oolitic. Crinoids (partially articulated) are the dominant fossil type of the Starr's Cave Member. A diverse assemblage of brachiopods is also present with lesser amounts of blastoids, starfish, corals, bryozoans, and trilobites reported. A total of 20 exposures (six quarries and 14 outcrops) of this map unit were observed in the mapping area.			
		Devonian	Upper	Famennian	English River Formation (Der)					[Symbol]	< 25	<b>Der - Siltstone and Shale</b> - The English River Formation ranges from 3 to 8 m (10-25 ft) thick in the mapping area. This unit is dominated by gray to olive green siltstone, locally shaly, with distinct botryoidal fabrics. Bryozoa and brachiopods are common, especially in the upper beds, with scattered abundant fossil molds as well. A total of six exposures (two quarries and four outcrops) of this unit were observed within the mapping area.		
						Famennian	Saverton Shale Formation (Dss)	[Symbol]	< 160		<b>Dss - Shale</b> - The Saverton Shale Formation can be up to 49 m (160 ft) thick in the mapping area. This unit is dominated by green to olive green siltstone, locally shaly, with sparse to absent macrofossils. Only one outcrop of this unit has been reported within the mapping area.			
									Famennian		Grassy Creek Formation (Dgc)	[Symbol]	< 180	<b>Dgc - Shale</b> - The Grassy Creek Formation can be up to 55 m (180 ft) thick in the mapping area. This unit is dominated by reganitic-rich brown shale with minor green-gray shale in the upper part of the unit. Divergent bedding between the Grassy Creek and overlying Saverton Shale was primarily based on color and relative abundance of spore cuticles identified in well cuttings. Exposures of this map unit were not identified within the mapping area.

## ACKNOWLEDGEMENTS

Special thanks to the private landowners who allowed access to their properties: Doug Beckman, Kirk Beckman, Carol Brandt, Mike Collentine, Doug Fenton, Dale Frank, Ernest Gerst, Dennis Gibbs, Teresa Johnson, and Steve Nunikhoven. Thanks also to Chris Lee (Des Moines County Conservation Board), Jeff Hanan (Des Moines County land use administrator), U.S. Gypsum, and Joe Halfer and Amanda Smith (Iowa Army Ammunition Plant). Don Smith (Cessford Construction - Oleclate Materials) and Brad Helmerston (L&W Quarries) are thanked for allowing us to access their quarries within the mapping area. University of Iowa (UI) Department of Earth and Environmental Sciences (EES) students Emily Copple, Tanner Hartsock, Brennan Hill, Diar Ibrahim, Nick Johnson, Hanna Konavalk, and Nick Letler helped with various aspects of data collection and management including producing descriptive logs of water well cuttings, updating well locations, and geophysical data acquisition. Assistance with field activities was provided by former Iowa Geological Survey (IGS) staff Zachary Demantet and H. Paul Liu (retired) as well as UI-EES students Brittany Stolius and Clint Henning. Thanks to Rick Langell of the IGS for managing the Iowa geologic sampling database (GeoSam). Brian Witzke (IGS-retired), Associate Professors Brad Cramer and Emily Finner (UI-EES), and Illinois State University Professor James "Jeff" Day are thanked for their help with the stratigraphic research components stemming from this mapping project as well as many fruitful discussions about the geologic complexities of the tri-state region. Casey Kohrt and Chris Kahle of the Iowa Department of Natural Resources provided GIS technical help. Additional funding for students was provided by the National Science Foundation (NSF) Award #2119888 (NSF IUSE-GEO/IGS, GP-GO, Iowa Environmental Interdisciplinary Program). Administrative support was provided by Megan Delaney, Suzanne Doershub, Melissa Eckrich, Teresa Gaffey, Carmen Langell, and Rosemary Tiwart.
